ATAST Response # 06020

1.0 Abstract

The North Carolina Division of Air Quality (DAQ) responded to requests for emergency monitoring to assess air quality resulting from a fire at the Environmental Quality hazardous waste facility in Apex, North Carolina. DAQ staff took measurements at 15 locations using continuous, real-time monitors for total volatile organic compounds, lower explosive limits (LELs), oxygen levels, chlorine, nitrogen dioxide, nitric oxide, phosphine, carbon dioxide, hydrogen sulfide, sulfur dioxide, hydrogen chloride, hydrogen cyanide and ammonia. DAQ also measured meteorological parameters at a height of 10 meters. In addition, staff collected air samples from locations in the evacuated areas of Apex and analyzed those samples using gas chromatography/mass spectroscopy. Analytical methods identified typical air pollution components at extremely low levels (part per billion). Concentrations of these constituents posed no apparent short-term air quality hazards and assisted emergency officials determine if the public could re-occupy evacuated areas.

2.0 Introduction

Shortly before 10:00 p.m. on October 5, 2006, fire crews were alerted to investigate a 'gas leak' at the Environmental Quality (EQ) facility at 1005 Investment Boulevard in Apex. Upon investigation, emergency responders discovered a fire at the facility that swiftly escalated, engulfing the facility and resulting in explosions fed from material contained at the plant. EQ is a hazardous waste treatment facility possessing an operating permit to treat, store, and dispose of a variety of industrial wastes, paints, household and other chemical waste such as spent solvents, pesticides and herbicides.

The Air Toxics Analytical Support Team (ATAST) was contacted at 12:10 a.m. October 6, 2006, and requested by Raleigh Hazmat to respond with air monitoring assistance. Seven¹ ATAST members departed at approximately 1:34 a.m. and arrived at approximately 1:50 a.m., reporting to Incident Command (IC) at the Department of Corrections Warehouse location on Schieffelin Road. ATAST deployed a mobile air-monitoring laboratory, an air monitoring equipment trailer, and a mobile Fourier-transform infrared spectrophotometer (FTIR) to this location. -After reporting to the IC, they awaited further instructions.²

At 3:42 a.m. on October 6, IC relayed a concern that law enforcement in the area of U.S. Highway 64/NC 55 intersection; they requested air-monitoring data from that area to ensure the safety of people in a nearby shelter. ATAST was prepared to deploy at that

¹ Dr. J. Bowyer, Mr. M. Reid, Mr. T. Pasley, Mr. T. Crawford, Ms. K. Clevenger, Dr. J. Holland and Ms. L. Cherry.

² As required by the National Incident Management System (NIMS), after reporting to the IC, the team becomes an asset subject to the authority of the IC until released.

time, but the IC required an escort from a hazmat unit in daylight hours for safety purposes. The hazmat unit's purpose was to determine if the location was safe for entry and to give the green light for air monitoring to begin. Once daybreak occurred and the hazmat unit completed their preparations, ATAST was escorted to a point near the Hwy 64/Hwy 55 intersection. The hazmat unit went forward to check on the area, but ATAST did not receive notice that the area was released for monitoring. Traffic had resumed on Hwy 55, the westernmost border of the evacuation area. At approximately 5:50am, incident command was moved to Laura Duncan Road north of US 64W.

ATAST contacted IC for permission to begin monitor deployment, and IC approved that request at 7:00am. Air quality monitoring was conducted from approximately 7:30am October 6 until noon on October 7. Weather conditions evolved from dry, cool conditions with a predominately light east wind to cool, wet conditions near dawn with winds ranging from the northwest to northeast. Wet conditions precluded the potential use of the FTIR and the instrument was released from mobilization. ATAST completed a shift change on October 6 around noon.³

Monitoring during the first stages of the event - when it might have been possible to identify some of the initial, toxic air contaminants was delayed due to the timing of the request for air monitoring assistance and with concern for the safety of the hazmat unit and the ATAST staff.

3.0 Ambient Air Testing

ATAST air monitoring is of most benefit when:

- Air-monitoring activities can aid in characterizing the degree of the hazard facing responders and the public during initial stages of response
- It can provide technical assistance to responders with tools such as air dispersion modeling, chemical review or meteorology.
- The team can coordinate with and provide technical support for decision-making or for information purposes.
- It can provide ongoing evaluation of air quality as conditions change to determine if airborne concentrations of pollutants are sufficiently safe for public re-occupancy.

Early reports indicated that a cloud of green gas that was characterized as chlorine gas had formed prior to and following the explosions. News media reports described people's experiences from a range of odors to different visual descriptions of the smoke plume. Odors were described as "chlorine", "sweet", "burned-rubber", and the smoke plume described as "greenish", "black" or "yellow". The plume constituent of most interest to Incident Command was particulate matter (PM). Effective monitoring of PM under emergency response situations had previously been identified by ATAST as a need and PM monitors have been ordered but had not been delivered before this incident. ATAST was unable to provide PM monitoring during the response.

Once ATAST received clearance from Incident Command to begin monitoring, the objective was to determine if areas were safe for public re-occupancy. Incident Command allowed ATAST to begin monitoring around the perimeter of the

³ 8:30am Mr. J. Lowder, Ms. T. Colon
12:00pm Dr. R. Jordan, Ms. R. Barrows, Mr. G. Kangkolo, Mr. C. Bender

evacuation zones. The first monitoring location was sited at the most upwind location of the evacuation area with other sites gradually progressing closer to EQ. ATAST began one of three monitoring series using Rae Systems AreaRae® units. The AreaRae® units measured virtually continuous, near real-time values. While each unit measures total volatile organic compounds, lower explosive limits (LELs) and percent oxygen, the units are also individually configured to measure two additional chemicals. Measurements were made for chlorine, nitrogen dioxide, nitric oxide, phosphine, carbon dioxide, hydrogen sulfide, sulfur dioxide, hydrogen chloride, hydrogen cyanide and ammonia. Actual unit configurations are detailed in Table 6. Tables 1, 2 and 3 show the locations where the units were placed and the time each unit operated. Table 4 is a summary of all fifteen locations. Figures 1-3 show their map locations. More than 14,300 data points from the AreaRae® units were obtained during the response.

To supplement the continuous measurements, eight discrete, or “grab,” air samples were taken by filling 6-liter Tedlar air-sampling bag at various locations on October 6 and 7. These samples were analyzed with an Inficon gas chromatograph/mass spectrophotometer (GC/MS) system on the mobile laboratory. During emergency air monitoring episodes the focus is usually on greater than part per million (ppm) concentrations of toxic materials. However, some chemicals can be toxic at very small quantities that may be difficult to detect with some of the less sensitive monitoring

instrumentation used during response situations. Samples having sufficient sample volume after analysis by the Inficon GC/MS were analyzed a second time at the ATAST main laboratory in Raleigh, NC with a Varian Saturn 2000 GC/MS system having a lower detection level. Each sample was analyzed for a suite of 57 volatile organic compounds on both GC/MS systems. Table 5 is a listing of these sample locations and further discussion of the results are found elsewhere in this report.

The Incident Commander released ATAST from service at approximately 2:45 p.m. on October 7, 2006.

4.0 Air Sampling Data and Analysis

Air sampling was conducted in three distinct series of locations in the surrounding community using AreaRae samplers and Tedlar air sampling bags. These areas are shown in Figures 1-3. Meteorological data was also collected at the Mobile Air Monitoring Laboratory vehicle (MAML) at the two incident command centers and used to produce wind speed and direction graphs (wind roses Figures 4 to 9) and to correlate the wind direction to the sampling data.

In each series, AreaRaes were deployed at the various locations as shown in the figures and had the following configuration of sensors.

Table 6 AreaRae[®] Sensors and Sampling Locations

| AreaRae | Sensors* | Series 1 | Series 2 | Series 3 |
|---|--|---|-------------------------------|----------------------------|
| 1 | Nitrogen dioxide (NO ₂) Nitrogen oxide (NO) Volatile Organic Compounds (VOC) Oxygen (O ₂) | Hwy 55 (Williams St) & Olive Chapel St. | Salem St. & West Moore St. | Tingen St. & Salem St. |

| * Lower Explosion Limit (%LEL) was also monitored but was not pertinent given that the value is based on a known single compound being present in order to calculate a % value (this was not generally the case in fire related incidents) and O ₂ levels were not abnormal. | | | | |

Figure 1 – Map of Series 1 Sampler Locations

Figure 2 – Map of Series 2 Sampler Locations

Figure 3 – Map of Series 3 Sampler Locations

4.1 Meteorological Data

Meteorological data were used to produce the following wind roses. The wind direction is plotted as the direction from which the wind is blowing towards the sampling station. The meteorological data are divided into periods that correspond to the time periods from the beginning of the incident to ATAST meteorological station deployment through the individual sampling series and to the end of the deployment. As can be seen in the figures, the winds were changing direction associated with a low pressure from the southeast late on Thursday October 5 to the north and northeast quadrant through the event. This had the effect of pushing the plume associated with the incident initially to the northwest then gradually to the west and then south. This influenced the areas and extent of the evacuation.

**Figure 4 Meteorological Data from Hadden Hall, Apex, NC
WeatherUnderground Station
October 5, 2006 9:00pm to October 6, 2006 3:00am**

**Figure 5 Meteorological Data at Incident Commands 1 & 2
IC 1 at DOC Warehouse Scheffelin Rd, IC2 at Laura Duncan Rd/US 64W
October 6, 2006 from 3am - 7:30am**

**Figure 6 Meteorological Data at Incident Command 2
October 6, 2006 7:30am - 10:00am**

**Figure 7 Meteorological Data Incident Command 2
October 6, 2006 10:00am - 1:30pm**

The wind roses are read in the following manner: the central number is the percentage of data points that are less than the lowest range value, in this case winds below 1 mph. The overall ray lengths represent the percentage of the data points when the wind was from that particular direction and the individual sections of the ray indicate the percentage of the data points when the wind was within that particular wind speed range (as indicated by the color and width of the ray shown in the key at the bottom of the figure). Example: Figure 9, winds were never below 1 mph (0%) during the sampling time. Winds came from the north 28% of the time and of that 28%, approximately 4% were 2-5mph, 23% were 5-10mph, and 1% were 10-15mph.

4.2 Continuous Monitoring Results

The results of the continuous monitors are presented in the following sections and are divided into the three series of sampling locations. The results are presented in Figures 10 to 57 and present the collected data from the various AreaRae monitors. On these figures it can be seen that no monitored concentration reached the Reference Exposure Limits (REL). A discussion of these RELs follows.

An examination of the ammonia data for AreaRae 2 (located at Jaycee Park entrance) and AreaRae 4 (located at the Apex Funeral Home) (see Figures 13 & 19), shows elevated ammonia concentrations at both locations, although not for the same time period. When coupled with the meteorological data (wind speed, wind direction) for the same time period (see Figures 25 and 27), it is observed that these ammonia measurements are not related to the EQ fire; rather they result from some other, uncharacterized source. It should also be noted that while ammonia measurements are elevated, one-hour averages of these measurements are approximately 1/3 of the screening level established for ammonia.

4.2.1 Reference Exposure Limits

Five-second and one minute data air data for airborne toxic vapors or gases, collected by the AreaRae[®] samplers must be compared with “reference exposure levels” for these chemicals in order to be able to determine the extent to which humans were exposed to these chemicals during the time of the incident. The primary “reference exposure levels” selected are those developed by the California Environmental Protection Agency (CalEPA), and are called California Acute Reference Exposure Levels (CaRELs)¹. CaRELs were selected as primary screening levels because they are generally more protective than Acute Exposure Guidelines (AEGl) and Emergency Response Planning Guidelines (ERPG), and are based on human health outcomes resulting from airborne releases “...including actual or potential spilling, leaking pumping, pouring, emitting, emptying, discharging, injecting, escaping, leaching, dumping, or disposing of a substance into the ambient air and that results from routine operation of a facility or that is predictable, including, but not limited to continuous and intermittent releases and predictable process upsets and leaks.”² CaRELs, unlike AEGls and ERPGs, are not limited to emergency releases. CaRELs, except those derived for a reproductive or developmental endpoint, are based on an averaging time of one hour.

For those chemicals for which a CaREL does not exist, a one-hour AEGl-1 will be used as the reference exposure levels. If an appropriate AEGl does not exist, then a one-hour ERPG-1 will be used.

AEGls are developed and revised by the U.S. Environmental Protection Agency.³ There are three AEGl levels:

AEGl-1: the airborne concentration of a substance above which it is predicted that the general population, including susceptible individuals, could experience discomforting, but not disabling, effects that are transient and reversible upon cessation of exposure.

AEGL-2: the airborne concentration of a substance above which it is predicted that the general population, including susceptible individuals, could experience irreversible or other serious, long-lasting adverse health effects or an impaired ability to escape.

AEGL-3: the airborne concentration of a substance above which it is predicted that the general population, including susceptible individuals, could experience life-threatening health effects or death.

AEGL-1 was selected as an REL candidate because it is the most protective of human health.

ERPGs (Emergency Response Planning Guidelines) are developed and revised by SCAPA⁴ (Department of Energy Subcommittee on Consequence Assessment and Protective Actions) and are intended to provide estimates of concentration ranges where one reasonably might anticipate observing adverse effects of human exposure.

ERPG-1: the maximum airborne concentration below which it is believed that nearly all individuals could be exposed for up to 1 hr without experiencing other than mild transient adverse health effects or perceiving a clearly defined, objectionable odor.

ERPG-2: the maximum airborne concentration below which it is believed that nearly all individuals could be exposed for up to 1 hr without experiencing or developing irreversible or other serious health effects or symptoms which could impair an individual's ability to take protective action.

ERPG-3: the maximum airborne concentration below which it is believed that nearly all individuals could be exposed for up to 1 hr without experiencing or developing life-threatening health effects.

ERPG-1 was selected as an REL candidate because it is the most protective of human health.

For the AreaRAE data collected during the EQ Apex Chemical fire, the Table 7 of RELs was developed:

Table 7 Reference Exposure Limits

| Chemical | Formula | CaREL (ppm) | AEGL-1 (ppm) | ERPG-1 (ppm) |
|-------------------------|-----------------------|------------------------|-------------------------|-------------------------|
| Ammonia | NH₃ | 4.6 | | |
| Carbon Monoxide | CO | 20 | | |
| Chlorine | Cl₂ | 0.07 | | |
| Hydrogen Cyanide | HCN | 0.31 | | |
| Hydrogen Sulfide | H₂S | 0.03 | | |
| Nitric Oxide | NO | 0.08 | | |
| Nitrogen Dioxide | NO₂ | 0.25 | | |
| Phosphine | PH₃ | Not available | 1.0* | |
| Sulfur Dioxide | SO₂ | 0.25 | | |

- Due to insufficient data, an AEGL-1 value has not been established. The AEGL-2 value is considered to be not sufficiently protective; therefore a value of one-half of the one-hour AEGL-2 is used. NO RELs are needed for VOC, LEL, and OXY data.

4.3 Grab Samples

As stated earlier in this report, to supplement the continuous measurements, eight discrete air samples were taken by filling 6-liter Tedlar air-sampling bag at various locations on October 6 and 7. These samples were analyzed with an Inficon gas chromatograph/mass spectrophotometer (GC/MS) system on the mobile laboratory. During emergency air monitoring episodes, the focus is usually on concentrations of toxic materials greater than part per million (ppm). However, some chemicals can be toxic at very small quantities that may be difficult to detect with some of the less sensitive monitoring instrumentation used during response situations. Samples having sufficient sample volume after analysis by the Inficon GC/MS were analyzed a second time at the ATAST main laboratory in Raleigh, NC with a Varian Saturn 2000 GC/MS system having a lower detection level. The summarized results are presented in the following section.

4.4 Wipe Sampling

After the fire was extinguished, DAQ conducted exterior wipe sampling at a selected number of homes, schools, and businesses for metals, semi-volatile organic chemicals, and cyanides. Wipe sampling for metals was conducted using ghost wipes (cotton towelettes moistened with de-ionized water); semi-volatiles were sampled using glass fiber filters dampened with de-ionized water; and cyanides were sampled with cellulose filters dampened with de-ionized water. The results of this sampling project will be discussed in the Exterior Wipe Sampling Report that will be published when these data are returned from the laboratory.

5.0 HEALTH IMPLICATIONS

The data presented in the Section 4.2 has been summarized in Table 8. These values were use to compare data to the RELs. NO RELs are needed for VOC, LEL, and OXY data.

Table 8 Summary of AreaRae® Data

| AreaRae 1 | Sampling Times | 1-hr average | | | | |
|-------------------------|----------------|--------------|-------------|-----|-------------|------|

| NC Average -- UAT 2002 to 2005 Average for Urban Sites | | | | | | |

RESULT: For some chemicals detected, the concentration range includes values in excess of the average NC urban air concentration. However, it should be stressed that **no airborne contaminant** collected and analyzed **exceeded 0.5%** of its reference exposure level.

6.0 SUMMARY

- For continuous monitoring, **no airborne contaminant for which sampling was conducted exceeded 33% of its reference exposure level.**
- For some chemicals detected in the grab samples, the concentration range exceeds the average NC urban air concentration. However, it should be stressed that **no airborne contaminant sampled and analyzed exceeded 0.5% of its reference exposure level.**
- Results from exterior wipe sampling will be published in a separate report when laboratory results have been received.
- Three sites have been established to continuously monitor the air during the remediation phase. Site 1 is approximately 0.2 miles SSW of EQ. Site 2 is approximately 0.2 miles E of EQ. Site 3 is approximately 0.25 miles NW of EQ. Continuous monitoring will be conducted for elemental mercury vapor, carbonyl compounds, volatile organic compounds (VOCs), and airborne particulate matter.
